#### **Deadlines**

Project 3 Released. Late Deadline: April 13, 2023. Report Grades Pending.

Project 4 Released. Initially Due: March 13, 2023Project 5 Released Due: April 13, 2023

All project work is due April 13, 2023. Late projects have a 75% score cap.

#### **Deadlines**

#### Alternate Path 1 & 2: Review in progress

- Piazza private threads need TLC
  - Weekly updates due each Monday @ 23:59 PT

#### Instructor Office Hours:

- Zoom Office Hours (Tuesday) @ 13:00-14:00
- Discord (Casual) Office Hours (Thursday) @ 14:00-15:00

TA Office Hours:

- Eric: Friday 9-11 am (in-person and Zoom)
- Japraj: Wednesday 3-5 pm (Zoom)
- Yennis: Thursday 2-4 (Zoom), Friday 2-4 (in-person)

### Readings

Required:

Recommended:

- In Search of an Understandable Consensus Algorithm
- Paxos vs Raft: Have we reached a consensus on distributed consensus (Video)

#### **Questions?**

Questions about the class?

Questions about the previous lecture?

Funny stories to share?

# **Today's Failure**

-

## Taking Too Long is Bad

This is my *personal* experience.

Project:

- A file server
- Multiple client computers
- A storage *fabric* (Fibre Channel)
  - Strongly interconnected
  - Storage is accessible from multiple machines

Goal: Use an existing file server (SMB on a Windows Server system) but allow direct storage usage on clients.

## **Taking too Long**

Server:

- Standard Windows Server
- SMB file server
- NTFS file system

#### Client:

- SMB Client (initially Windows)
- File system filter:
  - Capture *read* and *write* operations
  - Satisfy via direct I/O to attached storage

## Taking too long

Basic idea:

- File server owns metadata
  - File extension
  - File truncation
  - Location information (tunneled IOCTL query)
- Client:
  - Forwards size changing operations
  - Queries file server for *location* (tunneled IOCTL)
  - Direct I/O (read/write)

Benefit: file server is not a performance bottleneck

## What took too long?

Simple operation:

- Client application: extend the file by 10GB
- Client: request 10GB extension on file server
- Server: request NTFS extend file by 10GB
- NTFS: zero newly allocated storage region

#### Problem?

- It took > 600 seconds (10 minutes) to extend the file.
- Physical disk is slow
- Zero-filled disk region
- SMB protocol would time out after 10 minutes

### **Resolution: Don't take so long**

We fixed this by:

- Building a disk filter
- Detect when NTFS was extending
- Return immediately (do not zero disk)

Why was this OK?

- Zeroing the disk was a *security* features
- It was shared disk. The clients could already read it.
- Performance was more important than security

Result?

• System worked and was fast enough!

## **Lesson Goals**

-

**Review Paxos** 

Explain Raft Protocol

#### **Paxos Review**

Challenges

- How does Paxos work?
- Why does Paxos work?
- How to build a real system with Paxos?

Note: difficulty increases in that list above

### Why is Replication Difficult?

Partition: split brain challenge

- Primary and backup cannot communicate
- Clients can communicate with primary and/or backup

How to handle the failure:

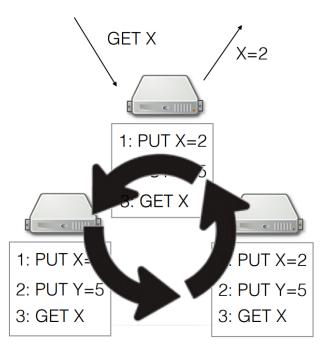

- Backup self-promotes
- Risk: Primary isn't dead
- Consistency lost

### **State Machine Replication (Example)**

Scenario:

- Three replicas, **no** primary, **no** view server
- Replicas maintain operations log
- Clients send requests to subset of replicas
- Replica **proposes** client request for consens
- Consensus:
  - Commit operation in log
  - Return result to client

#### Leaderless versus Leader

**Original Paxos** 

- Proposers, accepters, learners
- No leader
- Parallelism by running Paxos instance per log entry

#### Multi-Paxos

- Leader election (via original Paxos)
- Failure protocol: elect a new leader
- Leader handles commits (similar to 2PC)

Multi-Paxos is more popular for implementation. Project 4 is Multi-Paxos (because we need that for Project 5)

### **Original Paxos**

Each replica maintains an operations log

Client sends request to any replica

Replica initiates Paxos proposal

- Uses its latest sequence number
- Propose does not mean accepted

Proposers collect votes

- Quorum reached
  - Record in log
  - Return result to client

### **Practical Implementation Notes**

Replica normally consists of *Proposer, Accepter, and Learner* 

This is true for Project 4.

#### **Paxos: Reaching Agreement**

Client 42:

Sends Put(x)=42 to Server 1

Client 13

• Sends Put(x)=13 to Server 3

Cannot accept both values

We protect against partition by insisting on a quorum

### **Why Quorum Matters**

Recall: Paxos tolerates *f* failures.

This means we need 2f+1 replicas

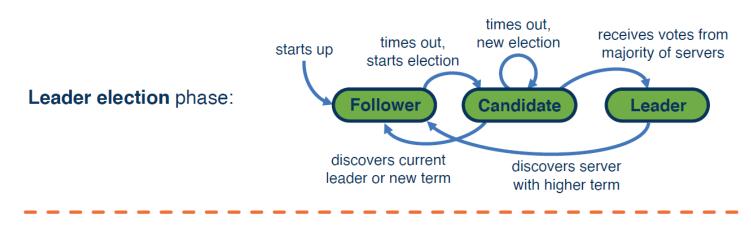

If *n* is the number of replicas, and *f* is the number of failures:

- Have to consider when we have *f* failures.
- Requires we have at least one non-failed case left

$$(n-f)-f \ge 1 \Rightarrow n \ge 2f+1$$

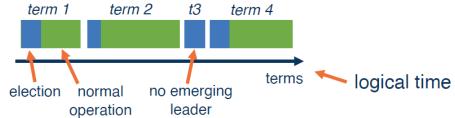

#### Raft

Followed by normal operation... Log Replication phase:

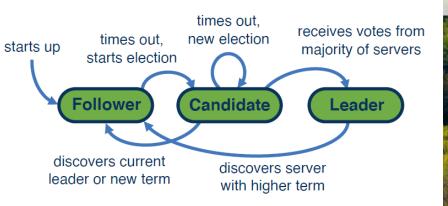

### **Raft: Leader Election Protocol**

Follower time-out: Call Election

#### Leader candidates "declare"

- Term Number
- Log Index
- (Isn't this just a view proposal?)

All nodes vote ("accepters")

#### **RAFT Leader Election Rules**

Property 1: At most one leader per term

Rule 1: Leader has Quorum ("majority")

• New term, Candidate becomes leader

#### Rule 2: Block old leaders

- Node: only vote for a candidate if their log is newer
- Could be same term number: log just longer
- Higher term number: new log
- Losing candidate: just another follower

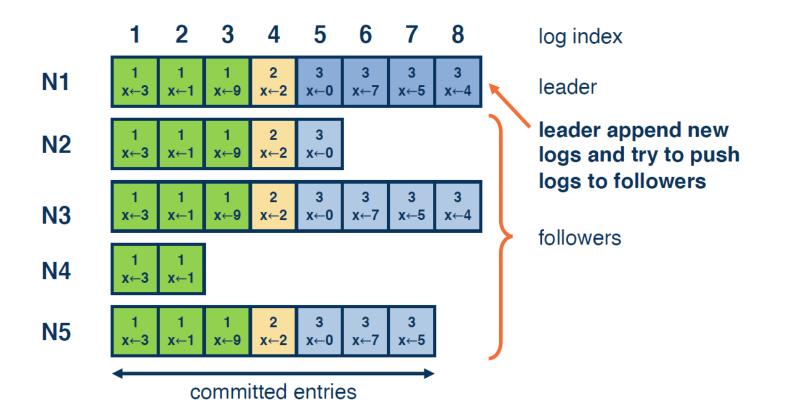

#### Rule 3:

- No winner/network partition? Try again
- Random timeouts to minimize split vote risk

log index

26

each log entry contains the operation and term number

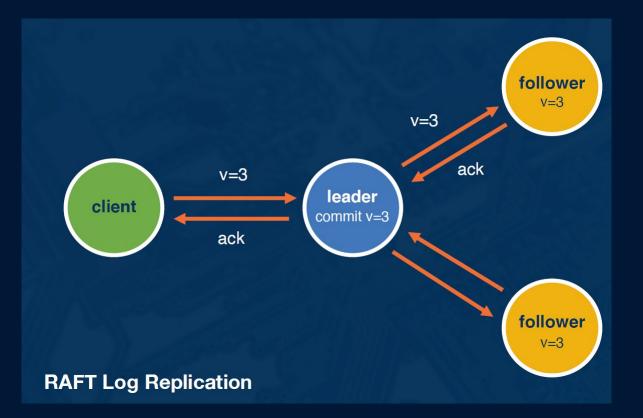

Step 1: Leader pushes new log entry + previous entry to followers (heartbeat)

Step 2: If follower has previous log entry: sends ack to leader

Step 3: Leader commits log entry once has quorum; send ack to client

Note: outdated followers catch up via heartbeat.

#### **Raft Leader Properties**

Append only

#### Log matching:

• If two entries in different logs have same index and term, all entries up to this point are the same.

#### Inconsistency:

- New leader does not know uncommitted log entries
- All followers must use new leader's log
- Leader election algorithm ensures new leader knows all *committed* logs

New leader commits uncommitted logs from previous terms *after* committing at least one log from current term.

### **Raft: Garbage Collection**

#### Log length grows

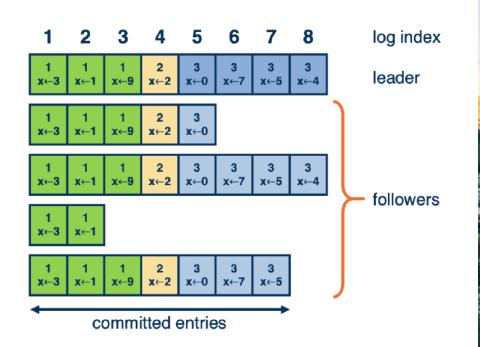

- Execution duration
- Nodes falling behind

#### Garbage collection:

- Snapshot
- Log truncation

#### **Recovery Optimization:**

 Leader sends snapshot via heartbeat

31

### **Raft Safety**

Property: Leader complete

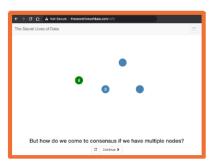

• Log entires not overwritten after commit

Property: State machine safety

• Log entry never overwritten in a node (see paper for formal proof)

Pat implementations
What is Raft?
Platt is a consensua algorithm that is designed to be easy to understand. It's equivalent to have in fuul-tolerance and performance. The difference is that it a decomposed the wildowly independent subproteinal, and it dearly addression all regimes models the practical indexet. Whe team that it main comparison handlab to be addre authorized, and that this webs address will be able to develop a summly of right regardly consensua-based system it has an example today.
